

TITLE

SYSTEM AND METHOD FOR ACQUIRING SEMICONDUCTOR PROCESS STATUS

INFORMATION

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to a system for acquiring semiconductor process status information, and in particular to a system and method for converting semiconductor process status information to standard industrial protocol.

10 Description of the Related Art

It is important for semiconductor manufacturers to maintain yield and quantity of output from semiconductor equipment. Monitor procedures comprise acquiring semiconductor process status information on demand.

15 Semiconductor manufacturers utilizing computer integrated manufacturing systems normally acquire semiconductor process status information through SECS/GEM protocol, but some status values are not obtainable thereby, and must be acquired by external sensors, and manually reported.

20 Computer integrated manufacturing systems cannot, therefore, acquire complete semiconductor process status information from semiconductor equipment installations through SEC/GEM protocol. Operations are often missed thereby, decreasing efficiency and creating many potential problems, 25 including possible production stoppage.

SUMMARY OF THE INVENTION

Accordingly, an object of the present invention is to provide a system and method for acquiring semiconductor process

status information and providing the acquired values to an equipment server.

To achieve the above object, the present invention provides a system for acquiring semiconductor process status information, 5 comprising an equipment server, a computer system server, a protocol converter, an AD/DA module and an external sensor.

An equipment server outputs a start command according to a HSMS (High Speed SECS Message Service) protocol. A computer system server connected to the equipment server converts the 10 start command from the HSMS protocol to a RS232 protocol and outputs the converted start command to a protocol converter, which then converts the start command from the RS232 protocol to a RS485 protocol. The converted start command is then output to an AD/DA module for conversion to an analog signal. An external 15 sensor is connected to the AD/DA module for acquiring semiconductor equipment status information as initiated by the start command. The external sensor outputs the status information to the AD/DA module, which converts the status information from the analog signal to the RS485 protocol and 20 outputs the converted status information to the protocol converter. The protocol converter converts the status information from the RS485 protocol to the RS232 protocol and outputs the converted status information to the computer system server. The computer system server converts the status 25 information to HSMS protocol and outputs the converted status information to the equipment server.

According to a method for acquiring semiconductor process status information, first a tool application program outputs a start command according to a first protocol. Then, the start 30 command is converted from the first protocol to a second protocol and outputting the converted start command. Thereafter, the

start command is converted from the second protocol to a third protocol and output. The start command is then converted from the third protocol to an analog signal and output. An external sensor is activated by the start command. The external sensor 5 acquires at least one semiconductor process status information. Thereafter, the status information is converted to the third protocol and output. Then, the status information is converted from the third protocol to the second protocol and output. The status information is converted from the second protocol to the 10 first protocol, and output to an equipment server.

A detailed description is given in the following embodiments with reference to the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention can be more fully understood by 15 reading the subsequent detailed description and examples with references made to the accompanying drawings, wherein:

Fig. 1 is a schematic diagram showing the architecture of the system for acquiring semiconductor process status information according to the present invention;

20 Fig. 2 is another schematic diagram showing the architecture of the system for acquiring semiconductor process status information according to the present invention;

Fig. 3 is a flowchart illustrating the method for acquiring 25 semiconductor process status information according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

Fig. 1 is a schematic diagram showing the architecture of the system for acquiring semiconductor process status information according to the present invention.

A system for acquiring semiconductor process status information comprises an equipment server 10, a computer system server 20, a protocol converter 30, an AD/DA module 40, a first external sensor 50, and a second external sensor 52.

5 An equipment server 10 outputs a start command according to a HSMS protocol and receives semiconductor process status information according to the HSMS protocol.

A computer system server 20 is connected to the equipment server 10 for converting the start command from the HSMS protocol 10 to a RS232 protocol and outputting the converted command. The computer system server 20 receives semiconductor process status information according to the RS232 protocol.

A protocol converter 30 is connected to the computer system server 20 for converting the start command from the RS232 protocol 15 to a RS485 protocol and outputting the converted command. The protocol converter 30 converts semiconductor process status information from RS485 protocol to RS232 protocol and outputs the converted information to the computer system server 20.

An AD/DA module 40 is connected to the protocol converter 20 30 for converting the start command from the RS485 protocol to an analog signal and outputting the converted command to the first external sensor 50 and the second external sensor 52. The AD/DA module 40 converts semiconductor process status information from the analog signal to the RS485 protocol and outputs the converted 25 information to the protocol converter 30.

A first external sensor 50 and second external sensor 52 are connected to the AD/DA module 40 for acquiring semiconductor equipment status information as initiated by the start command. The first external sensor 50 and second external sensor 52 acquire 30 semiconductor process status information such as standard current input $\pm 4\text{~}20\text{mA}$ and voltage input $\pm 15\text{mV}$. The first

external sensor 50 and second external sensor 52 both send semiconductor process status information to the AD/DA module 40.

Fig. 2 is another schematic diagram showing the architecture of the system for acquiring semiconductor process status 5 information.

A system for acquiring semiconductor process status information comprises external sensors 100-190, AD/DA modules 200-290, protocol converters 300-390, a computer system server 500, a COM port box 510 and equipment servers 600-690.

10 Equipment servers 600-690 send a start command to the computer system server 500, and receive semiconductor process status information from the computer system server 500, both according to HSMS protocol.

15 The computer system server 500 comprises a first COM port 400 and a second COM port 410. The first COM port 400 and the second COM port 410 are RS232 COM port. The COM port box 510 comprises COM ports 420-490. Typically, computer system server 500 can support a number of protocol converters corresponding to available COM ports.

20 The protocol converters 300-390 convert a start command from the RS232 protocol to the RS485 protocol, and output the converted command to corresponding AD/DA modules. In the reverse operation, the protocol converters 300-390 convert semiconductor process status information from the RS485 protocol to the RS232 25 protocol and output the converted information to corresponding computer system server 500.

AD/DA modules 200-209 are connected to the protocol converter for conversion of the start command from RS485 to analog and output of the converted command to a corresponding external 30 sensor, as well as, in the reverse operation, conversion of the

start command from analog to RS485 protocol and output of the converted information to corresponding protocol converter.

External sensors 100-109 acquire semiconductor process status information in response to the start command, and output 5 information to a corresponding AD/DA module.

Semiconductor process status information can include temperature, pressure, flow rate, consistency, rotational speed, voltage value, and electric current value, with standard voltage value of $\pm 15mV$, $\pm 50mV$, $\pm 100mV$, $\pm 150mV$, $\pm 500mV$, $\pm 1V$, $\pm 2.5V$, $\pm 5V$ 10 or $\pm 10V$. Standard current input is $\pm 0\sim 20mA$ or $\pm 4\sim 20mA$. Standard direct sensor input is thermocouple (J, K, T, E, R, S, B type) or RTD (Pt, Ni, Balco). Standard digital input is high or low (0/1).

Fig. 3 is a flowchart illustrating the method for acquiring 15 semiconductor process status information.

First, in step S700, a tool application program in an equipment server outputs a start command according to HSMS protocol to request semiconductor process status information from an external sensor. The external sensor outputs requested 20 information to the equipment server. A reading time is set up for the tool application program, wherein the equipment server outputs a start command corresponding to HSMS protocol regularly according to the preset time.

In step S710, a computer system server outputs the start 25 command. The computer system server converts the start command from HSMS protocol to a RS232 protocol and outputs the converted command to a protocol converter.

Then, in step S720, the protocol converter converts the start command from RS232 protocol to a RS485 protocol and outputs 30 the converted command to an AD/DA module according to the RS485 protocol.

In step S730, the AD/DA module outputs the start command to an external sensor. The AD/DA module converts the start command from the RS485 protocol to an analog signal and outputs the converted command to the external sensor.

5 In step S740, the external sensor acquires semiconductor process status information, in response to the start command. The external sensor acquires status information and outputs the information to the AD/DA module.

Then, in step S750, the AD/DA module outputs status 10 information to the AD/DA module. The AD/DA module converts status information from the analog signal to the RS485 protocol which can be accepted by protocol converter. The AD/DA module outputs the converted status information to the protocol converter.

In step S760, the protocol converter converts status 15 information from the RS485 protocol to the RS232 protocol, suitable for processing by the computer system server, and outputs the converted status information thereto.

In step S770, the computer system server outputs status information via COM port to the equipment server.

20 Finally, in step S780, the equipment server outputs status information to the computer integrated manufacturing system according to SECS/GEM protocol.

According to the present invention, a system and method for acquiring semiconductor process status information, a computer 25 system server, protocol converter, AD/DA module, and external sensor, via COM port of the computer system server, connect to the equipment server and restart it. Thus, equipment server downtime almost is significantly decreased, increasing output and productivity.

30 The present invention provides a system and method for acquiring semiconductor process status information. The

computer integrated manufacturing system via standard automation protocol conversion (SECS/HSMS/GEM) requests the external sensor to acquire semiconductor process status information and returns the acquired values to the computer integrated manufacturing system, enabling semiconductor equipment installations to prevent missed operation.

5 While the invention has been described by way of example and in terms of the preferred embodiments, it is to be understood that the invention is not limited to the disclosed embodiments. To 10 the contrary, it is intended to cover various modifications and similar arrangements (as would be apparent to those skilled in the art). Therefore, the scope of the appended claims should be accorded the broadest interpretation so as to encompass all such modifications and similar arrangements.
